Concepts

Main concepts and definitions

1. Magnetic field

Current induces magnetic field. In spiral coils, the magnetic field (H) induced by current can be expressed as:

$$H = \frac{NI}{l}$$

Where all parameters are in SI unit system and N is turn number, I (A) is current, l (m) is the length of the spiral coils.

In magnetic core, the field strength H induced by alternate current can be calculated in term of the effective length of the spiral coils:

$$H = \frac{\sqrt{2} IN}{le} \text{ (A/m)}$$

$$1Oe = \frac{1 \times 10^3}{4\pi} \approx 79.584 \text{ m}$$

2. Magnetic flux density, magnetic polarizability, magnetization. In magnetic material, the magnetic flux density varies as applied field H . It behaviors as:

$$B = \mu_0 H + J \text{ or } B = \mu_0 (H+M)$$

Where B is magnetic flux density also called magnetic induction, J magnetic polarization, M magnetization, and μ_0 vacuum permeability with the value of $4\pi \times 10^{-7}$ H/m. The units of B and J are Tesla (T) and those of H and M are A/m.

1 Tesla = 10^4 Gauss

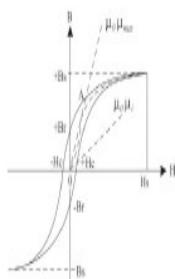

In magnetic cores, the magnetic flux density can be calculated using effective area A_e :

$$\hat{B} = \frac{0.225V}{fMe} \text{ For sine wave}$$

Where V is electric potential in Volt, f frequency in Hz, N turn number, \hat{B} in mT and A_e in m^2 .

3. Saturation magnetization, remanent magnetization, and coercivity.

Besides the linear relation between B and H in vacuum, B behaves a nonlinear relation as H in magnetic materials displaying the hysteresis shown in the figure.

In the figure, B_s is saturation induction, B_r residual induction, H_c coercivity, and H_s saturation field.

Different magnetic materials display various hysteresis, leading to different B_s , B_r , H_c , and H_s .

4. Impedance

Inductive impedance in an electric inductance is $X_L = j\omega L$, and condenser impedance in a condenser is $X_C = \frac{1}{j\omega C}$.

These two are generally called electrical impedance. Adding pure resistance R , they are in all called impedance. In magnetic devices, we only consider inductive impedance and pure resistance for the issue of relative low frequency, neglecting condenser impedance. There is the difference between serial and parallel circuit.

Series representation

Parallel representation

$$\text{Series representation } Z = R + j\omega L$$

$$\text{Parallel representation } Z_p = \frac{1}{1/(j\omega L_p) + 1/R_p}$$

Z and Z_p depend on frequency, and their characteristics are called impedance frequency characteristics and related to the frequency characteristics of magnetic materials, and they are connected with winding parameters. In complex permeability, its frequency characteristics is determined by the frequency characteristics of both μ and μ' . Actually, the impedance frequency characteristic is the characteristic of the magnetic device but the characteristic of material.

5. Quality factor Q

When magnetic device is used as electric inductance in wave filter, its property is usually characterized using quality factor Q .

$$Q = \frac{1}{tg \delta} = \frac{\omega L}{R_{tot}}$$

When R_{tot} is total resistance including coil and core resistance. R_{tot} indicates loss including magnetic core loss and core loss and copper wire loss. Q value is closely related to frequency and coil parameters.

6. Electric inductance factor AL

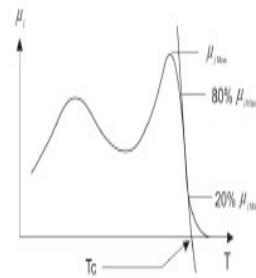

The inductance value of an electric inductance or a transformer with N turn coils is L . It defines that $AL = \frac{L}{N^2}$. When the unit AL is $\frac{nH}{N^2}$, taking $N=100$ commonly, but sometimes the parameter of AL is not used, because when the turns of winding are too many and in circumstance of closed magnetic circuit the magnetic field is likely to enter resonance area or approach saturation area.

$$AL = \frac{\left[\text{Set } L(nH) \right]^{1/2}}{\left[AL(nH/N^2) \right]}$$

When without the gap, $\mu_i = \frac{C_1}{0.4} AL$, where C_1 of core parameters is mm^{-1} , AL is $\frac{nH}{N^2}$. AL value is related to the size and surface roughness of the gap. If known AL value and magnetic core size, one can easily obtain permeability μ_i used material.

7. Curie temperature

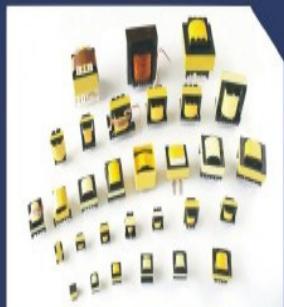

Curie temperature is the transition temperature of magnetic materials from ferromagnetism to paramagnetism. There are several methods to determine Curie temperature. The method is shown as the following figure.

As temperature increases, one can find the two points with the permeability falling down to 80% μ_{max} and 20% μ_{max} respectively. Connecting the two points and extrapolating the line to T axis, the point of intersection is Curie temperature.
